TITLE OF THE INVENTION

[0005]   ONE-CYLINDER STACK CAPACITOR AND METHOD FOR

FABRICATING THE SAME

BACKGROUND OF THE INVENTION

1.   Field of the Invention

[0010]   The present invention generally relates to one-cylinder stack (OCS)

capacitors and to methods of fabricating the same, and more particularly, the present

invention relates to OCS capacitors which have been formed from a double-mold,

and to methods of fabricating OCS capacitors using a double-mold.

2.   Description of the Related Art

[0015]   As semiconductor devices increase in memory cell density, the area

occupied by capacitors of the memory cells has decreased.   Capacitance is

proportional to the dielectric constant of the capacitor dielectric and to the surface

area of the capacitor electrodes.   Thus, to increase capacitance, it is necessary to

either select a dielectric of increased dielectric constant and/or to increase the

1   surface area of the capacitor electrodes.   However, adopting n w diel ctric

2   materials is generally expensive and time-consuming in that it is often necessary to

3   supply new manufacturing equipment, to verify the reliability of the dielectric

4   materials, and to ensure the ability to mass produce devices having the dielectric

5   materials.   Therefore, increasing the surface area of electrodes is usually the most

6   cost-effective means of satisfying a requirement for increased capacitance of a

7   device having conventional dielectrics, such as dielectric (NO) layers composed of

8   a stack of silicon nitride and silicon oxide layers.

9   [0020]   Hemispherical grain (HSG) electrodes are used in conventional 128-Mbit

10 or less DRAMs to increase the effective surface area of the electrodes.   However,

11 these electrodes cannot be applied in highly integrated devices of 256-Mbit or

12 greater because any reduction in spacing between electrodes is limited due to the

13 presence of HSGs on the surface of the electrodes.   As such, in the case of a

14 one-cylinder stack (OCS) storage electrode, increasing the height of the electrode

15 from 1.4 µm to 1.6 µm, for example, has generally been considered the most efficient

16 means of increasing the capacitance thereof.

1 [0025]   The fabrication of a conventional OCS storage electrode will now be

2 described with reference to FIGS. 1-6.   In particular, an OCS capacitor storage

3 electrode having a design rule of less than 1.2 μm is typically formed using a single

4 mold.   Referring to FIG. 1, an etch stop layer (not shown) is formed on an interlayer

5 insulating layer 10 having a contact plug 15 in a surface thereof, and an oxide layer

6 (not shown) is formed to a thickness $h1$, which substantially corresponds to the

7 desired height of an electrode.   Next, the oxide layer and the etch stop layer are

8 sequentially etched into an oxide mold 30 having an underlying etch stop 20.   In this

9 manner, an opening 40 is defined over the contact plug 15, thereby exposing the

10 contact plug 15.   Then, as shown in FIG. 2, polysilicon is deposited on the sidewalls

11 of the opening 40 and on the contact plug 15 so that a cylindrical electrode 50 is

12 formed.

13 [0030]   Reference is made to the scanning electron microscopic (SEM)

14 photograph of FIG. 3.   As mentioned previously, to increase the capacitance in the

15 case of highly integrated devices, it is desired to increase the height of the OCS

16 capacitor storage electrode to 1.6 μm or greater.   However, noting that etching

1   limitations set the slope of the sidewalls of the op ning 40, if the height of the oxide

2   mold layer is increased from *h1* to *h2* (about 1.8 µm) and a lower critical dimension

3   (d) of the opening 40 is maintained, a bridge B (FIGS. 2 and 3) may be formed

4   between neighboring OCS capacitor storage electrodes, thereby causing a twin-bit

5   failure.   In an effort to avoid twin-bit failures, the upper critical dimension (a) of the

6   opening 40 can be reduced by reducing the lower critical dimension (d) of the

7   opening 40.   However, this approach is disadvantageous in that the surface area at

8   the bottom of the opening 40 is reduced, thereby reducing capacitance.

9   **[0035]**   It is also noted that twin-bit failures can occur as a result of storage

10   electrodes falling down and contacting adjacent electrodes.   As such, consideration

11   must be given to the structural integrity of the electrodes.

12   **[0040]**   That is, referring now to FIG. 4, after separation of the storage electrodes

13   for cell isolation has been ensured, the oxide mold 30 is removed by wet etching.

14   During this wet etching process, an etchant can permeate into the interface between

15   each storage electrode 50 and an etch stop 20, thus etching the interlayer insulating

16   layer 10.   This can weaken the foundation of the storage electrode, causing the

1   storage electrode to tip over and contact adjacent electrodes.   FIG. 5A is a

2   scanning electron microscopic (SEM) photograph showing an example in which

3   falling electrodes have resulted in a depression having an @-shaped pattern, and

4   FIG. 5B is a scanning electron microscopic (SEM) photograph showing a

5   cross-sectional side view of electrodes falling into one another.

6   [0045]   Therefore, there is an increasing need for a new OCS capacitor structure

7   and a method for fabricating the same in which depressions and bridging between

8   adjacent electrodes can be effectively avoided even in the case where the capacitor

9   height is on the order of 1.6 µm or more.

10

11   SUMMARY OF THE INVENTION

12   [0050]   According to one aspect of the present invention, a method of fabricating

13   a capacitor electrode includes forming an etch stop layer over a surface of an

14   interlayer insulating layer and over a surface of a conductive plug extending at a

15   depth from the surface of the interlayer insulating layer; forming a lower mold layer

16   over the etch stop layer, and adjusting a wet etch rate of the lower mold layer by

1   adding dopants to the lower mold layer during formation of the lower mold layer, and

2   by annealing the lower mold layer; forming an upper mold layer over the surface of

3   the lower mold layer, wherein a wet etch rate of the upper mold layer is less than the

4   adjusted wet etch rate of the lower mold layer; dry etching the upper mold layer, the

5   lower mold layer and the etch stop layer to form an opening therein which exposes

6   at least a portion of the surface of the contact plug; wet etching the upper mold layer

7   and the lower mold layer so as to increase a size of the opening at the lower mold

8   layer and so at to expose a surface portion of the etch stop layer adjacent the

9   surface of the conductive plug; and depositing a conductive material over the

10   surface of the opening in the upper and lower mold layers, the surface portion of the

11   etch stop layer, and an exposed surface of the conductive plug.

12   [0055]   According to another aspect of the present invention, a method of

13   fabricating a capacitor includes forming a lower electrode over an interlayer

14   insulating layer, forming a dielectric layer over the lower electrode, and forming an

15   upper electrode over the dielectric layer.   Here, formation of the lower electrode

16   includes forming an etch stop layer over a surface of the interlayer insulating layer

1   and over a surface of a conductive plug extending at a depth from the surface of the

2   interlayer insulating layer; forming a lower mold layer over the etch stop layer, and

3   adjusting a wet etch rate of the lower mold layer by adding dopants to the lower

4   mold layer during formation of the lower mold layer, and by annealing the lower mold

5   layer; forming an upper mold layer over the surface of the lower mold layer, wherein

6   a wet etch rate of the upper mold layer is less than the adjusted wet etch rate of the

7   lower mold layer; dry etching the upper mold layer, the lower mold layer and the etch

8   stop layer to form aN opening therein which exposes at least a portion of the surface

9   of the contact plug; wet etching the upper mold layer and the lower mold layer so as

10   to increase a size of the opening at the lower mold layer and so at to expose a

11   surface portion of the etch stop layer adjacent the surface of the conductive plug;

12   and depositing a conductive material over the surface of the opening in the upper

13   and lower mold layers, the surface portion of the etch stop layer, and an exposed

14   surface of the conductive plug.

15   [0060]   According to still another aspect of the present invention, a capacitor

16   includes an interlayer insulating layer having a surface; a conductive plug extending

1   at a depth from the surface of the interlayer insulating layer; an etch stop layer

2   extending over the insulating layer and exposing the conductive plug; a cylindrical

3   lower electrode defined by a cylindrical wall and a bottom wall which extends over a

4   surface of the conductive plug and over a portion of the etch stop layer adjacent the

5   conductive plug, wherein the cylindrical wall extends upwardly from the bottom wall

6   away from the surface of the interlayer insulating layer; a dielectric layer formed over

7   the cylindrical lower electrode; and an upper electrode formed over the dielectric

8   layer.   The cylindrical wall of the cylindrical lower electrode is defined by an upper

9   cylindrical wall portion, a lower cylindrical wall portion, and an intermediate cylindrical

10   wall portion located between the upper and lower cylindrical wall portions.   A

11   diameter of the upper cylindrical wall portion and a diameter of the lower cylindrical

12   wall portion increase with an increase in a distance from the surface of the bottom

13   wall, and a diameter of the intermediate cylindrical wall portions decreases with an

14   increase in a distance away from the surface of the bottom wall, and

15     $$A \geq C, \quad C > B, \quad \text{and} \quad C > D$$

16   where A is a diameter of the upper cylindrical wall portion at a location farthest from

8

1 the bottom wall, B is a diameter of the upper cylindrical wall portion at a location

2 nearest to the bottom wall, C is a diameter of the lower cylindrical wall portion at a

3 location farthest from the bottom wall, and D is a diameter of the lower cylindrical

4 wall portion at the bottom wall.

5

6 BRIEF DESCRIPTION OF THE DRAWINGS

7 [0065] The above and other aspects and advantages of the present invention

8 will become more readily apparent from the detailed description that follows, with

9 reference to the accompanying drawings, in which:

10 [0070] FIGS. 1 and 2 are sectional views for explaining a conventional method for

11 fabricating a capacitor using a single mold;

12 [0075] FIG. 3 is a scanning electron microscopic (SEM) photograph of storage

13 electrodes manufactured by the conventional method;

14 [0080] FIG. 4 is another sectional view for explaining the conventional method

15 for fabricating a capacitor using a single mold;

[0085]   FIGS. 5A and 5B are SEM photographs taken from a top viewpoint and a side viewpoint, respectively, of storage electrodes fabricated by the conventional method;

[0090]   FIGS. 6 through 13 are sectional views for explaining a method for fabricating a one-cylinder stack capacitor using a double mold according to an embodiment of the present invention;

[0095]   FIG. 14 is a sectional view illustrating a defect that can occur when fabrication conditions of the present invention are not satisfied;

[0100]   FIGS. 15 through 17 are graphs comparatively showing the properties of capacitors fabricated by the conventional method using a single mold and by the method of the present invention using a double mold;

[0105]   FIGS. 18 and 19 are SEM photographs showing twin-bit failures observed in storage electrodes fabricated without cleaning the lower mold insulating layer; and

[0110]   FIG. 20 is a graph showing a relationship between wet etching time and certain critical dimensions of the electrodes of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0115]   Embodiments of the present invention will now be described with reference to the accompanying drawings.   It is noted that the drawings are presented for illustrative and explanatory purposes only, and are not necessarily drawn to scale.

[0120]   A method of fabricating a one-cylinder stack (OCS) capacitor according to the present invention will be described with reference to FIGS. 6-13.   As will be appreciated by those skilled in the art, the term "cylindrical" is used herein to denote a particular type of capacitor electrode having a generally circular, elliptical or oval sidewall (which may be slanted), and not to denote any precise geometric shapes which as defined in a purely mathematical sense.

[0125]   Referring first to FIG. 6, an interlayer insulating layer 100 and a contact plug 155 extending at a depth within the surface of the layer 100 are formed over a substrate (not shown) by known processes.   An etch stop layer 120 is then formed over the layer 100 and plug 155.   Lower and upper mold layers 130 and 135 are then successively formed over the etch stop 120 as shown.

1   [0130]   The etch stop layer 120 acts as an etch barrier during subsequent etching

2   (described later) of the upper and lower mold insulating layers 135 and 130 formed

3   thereon, and thus a material for the etch stop layer 120 is selected in consideration

4   of the etching properties of the upper and lower mold insulating layers 135 and 130.

5   As one example only, if the upper and lower mold insulating layers 135 and 130 are

6   oxide layers, the etch stop layer 120 may be formed of silicon nitride to a thickness

7   of 100-500Å.

8   [0135]   The upper and lower mold insulating layers 135 and 130 constitute a

9   double layer which will be etched into a double mold for fabrication of a lower

10   capacitor electrode.   The lower mold insulating layer 130 is formed of a material

11   which exhibits a greater wet etch rate than the material of the upper mold insulating

12   layer 135.

13   [0140]   The wet etch rate of an insulating material is influenced by the

14   concentration of dopants implanted into the same.   The larger the dose, the higher

15   the wet etch rate.   Accordingly, to achieve differing wet etch rates as mentioned

16   above, the lower mold insulating layer 130 may be formed of a doped insulating layer,

1   whereas the upper mold insulating lay r 135 may b form d of an undoped (or

2   lesser doped) insulating layer.

3   [0145]   Preferably, the lower mold insulating layer 130 is formed of a doped oxide

4   layer by chemical vapor deposition (CVD).   Suitable doped oxide layers include

5   borophosphosilicate glass (BPSG) and phosphosilicate glass (PSG).   Preferably,

6   the upper mold insulating layer 135 is formed of an undoped oxide layer by plasma

7   enhanced chemical vapor deposition (CVD).   Suitable undoped oxide layers include

8   plasma-enhanced tetraethylorthosilicate (PE-TEOS) layers, high-density plasma

9   (HDP) oxide layers, and $P-SiH_4$ oxide layers.

10   [0150]   The height H1 of the lower mold insulating layer 130 and the height H2 of

11   the upper mold insulating layer 135 are determined according to the target height of

12   the storage electrode to be fabricated and the etch properties of the upper and lower

13   mold insulating layers 135 and 130.   In particular, the height H1 of the lower mold

14   insulating layer 130 is determined such that an opening to be formed therein exhibits

15   certain upper and lower maximum diameters (described later).   For example, when

16   the lower mold insulating layer 130 is formed of a BPSG layer and the target height

1   of the fabricated storage electrode is 1.6 µm or greater, it is preferable that the height

2   H1 of the lower mold insulating layer 130 is in the range of 0.5-0.6 µm, and the

3   height H2 of the upper mold insulating layer 135 is in the range of 1.1-1.4 µm.   The

4   height H1 of the lower mold insulating layer 130 and the height H2 of the upper mold

5   insulating layer 135 will vary depending on the materials used for the insulating

6   layers and the target height of the fabricated storage electrode.

7   [0155]   After deposition of the lower mold insulating layer 130 and before

8   deposition of the upper mold insulating layer 135, the lower mold insulating layer 130

9   may be optionally subjected to annealing and/or surface cleaning processes.

10   [0160]   That is, the wet etch rate of the lower mold insulating layer 130 can be

11   controlled by annealing.   More specifically, implanting ions in the lower mold layer

12   130 for the purpose of increasing the wet etch rate can often result in the wet etch

13   rate being increased too much.   Annealing can be effectively used to more precisely

14   lower the wet etch rate after the implantation process.   As such, implantation

15   followed by annealing is an effective mechanism for fine tuning the wet etch rate.

16   For example, when the lower mold insulating layer 130 is formed of a BPSG layer

1   doped with boron (B) and phosphorous (P), each at a concentration of 2-3% by

2   weight, annealing is preferable to bring down the etch rate. On the other hand,

3   when the lower mold insulating layer 130 is formed of a PSG layer doped with P at a

4   concentration of no greater than 5% by weight, annealing of the lower mold

5   insulating layer 130 can be omitted.

6   [0165] The annealing itself is performed at a range of temperatures at which

7   cracking of the lower mold insulating layer 130 is avoided, and preferably, at a

8   temperature which is lower than the deposition temperature of the etch stop layer

9   120. For example, when the etch stop layer 120 is formed of a silicon nitride layer,

10   the lower mold insulating layer 130 is preferably annealed at a temperature of 700°C

11   or less.

12   [0170] After annealing, the lower mold insulating layer 130 may also be subjected

13   to a surface cleaning process. For example, when the lower mold insulating layer

14   130 and the upper mold insulating layer 135 are not formed in-situ, a considerable

15   amount of time may elapse from the formation of the lower mold insulating layer 130

16   to the formation of the upper mold insulating layer 135. In this case, moisture can

1   be absorbed by the dopants implanted into the lower mold insulating layer 130, thus

2   forming an amorphous defect layer on the surface of the lower mold insulating layer

3   130.   This amorphous defect layer can exhibit a wet etch rate which is greater than

4   the remainder of the lower mold insulating layer 130.   It is therefore preferable to

5   perform surface cleaning to remove the amorphous defect layer either after

6   annealing or after deposition of the lower mold insulating layer 130.   A sulfuric acid

7   solution may be used for this purpose.

8   [0175]   The cleaning process for removing the amorphous defect layer can be

9   omitted when the formation of the amorphous defect layer has been avoided in the

10   first place, i.e., when the lower mold insulating layer 130 and the upper mold

11   insulating layer 135 are formed in-situ, or when the lower mold insulating layer 130 is

12   exposed to air either not at all or for only a short period of time prior to deposition of

13   the upper mold insulating layer 135.

14   [0180]   Next, referring to FIG. 7, the upper mold insulating layer 135, the lower

15   mold insulating layer 130, and the etch stop 120 are sequentially dry etched using a

16   mask (not shown) to form an opening 140.   The dry etching may be carried out

1 using a CF_x gas, such as C_4F_4 or C_3F_8 gases. Process limitations of the dry etch

2 result in the opening 140 being defined by sidewalls which are slanted (not

3 perpendicular) relative to the surface of interlayer insulating layer 100. In other

4 words, the opening 140 tapers outwardly in a height direction such that a diameter of

5 the opening is greater at its top than at its bottom.

6 [0185] Referring now to FIG. 8, a selective wet etch is carried out to complete the

7 formation of a double mold 138. Since the lower insulating mold 130 is formed of a

8 material layer having a wet etch rate which is greater than the upper insulating mold

9 135, more of the lower insulating mold 130 is removed by the wet etch than the

10 upper insulating mold 135. As such, a vase-like opening 140' is defined in the

11 double mold 138 as shown. While the upper insulating mold 135 may be slightly

12 etched, this slight etching advantageously functions as a pre-cleaning prior to

13 formation of a storage electrode (described later). Preferably, the wet etching is

14 performed using SC1 (NH_4OH/H_2O_2/deionized water) and hydrofluoric acid (HF) in

15 sequence.

16 [0190] The wet etching is performed under conditions which achieve certain

1   designed dimensions within the opening 140', herein referred to as critical

2   dimensions A, B, C, D and E.   As shown in FIG. 8, A is the maximum width (or

3   diameter) of the opening 140' at the upper insulating mold 135; B is the minimum

4   width (or diameter) of the opening 140' at the upper insulating mold 135; C is the

5   maximum width (or diameter) of the opening 140' at the lower insulating mold 130; D

6   is the minimum width (or diameter) of the opening 140' at the lower insulating mold

7   130; and E is an exposed amount of the etch stop 120 at the bottom of the opening

8   140'. As examples, it is preferable that critical dimension C of the opening 140' is

9   equal to or smaller than a critical dimension A.   In addition, it is preferable that

10   critical dimension E is sufficient to prevent etchant from permeating into the

11   interlayer insulating layer during removal of the double mold 138 in a subsequent wet

12   process (described later).

13   [0195]   For example, to form a storage electrode having a height of 1.6 μm or

14   greater, it is preferable that the lower critical dimension D of the opening 140' is not

15   less than 145 nm and the exposed length E of the etch stop 120 is not less than 15

16   nm.

[0200] Other parameters that affect wet etching conditions for the double mold

138 include the concentration of dopants in the lower insulating mold 130 (i.e., the

etch rate of the material) and a wet etch time.

[0205] Referring to FIG. 9, a conductive layer 150 is formed so as to conform to

the sidewalls, bottom and the top of the double mold 138. The conductive layer 160

defines a lower electrode and may be formed of a polysilicon layer or a doped

polysilicon layer. A thickness F of the conductive layer 150 may be in a range of

30-60 nm, and in the case of a storage electrode having a height of 1.6 µm or

greater, the thickness F may be about 45 nm.

[0210] Next, as shown in FIG. 10, an insulating layer 160 is deposited on the

entire surface of the resultant structure using a material exhibiting good flowability,

for example, BPSG, PSG, or undoped silicate glass (USG), to fill the opening 140'.

Then, as shown in FIG. 11, the insulating layer 160 and the conductive layer 150 are

partially removed by chemical mechanical polishing (CMP) or dry etchback until a

top of the double mold 138 is exposed.

[0215] Next, as shown in FIG. 12A, the double mold 138 and the insulating layer

1   160 are removed using an etchant so that a storage electrode 150 having a

2   one-cylinder stack structure is formed for each cell. In removing the double mold

3   138, a mixture of HF and NH_4F is preferably used as the removal etchant. Here,

4   since the conductive layer 150 overlaps the etch stop 120, the etchant must travel a

5   substantial distance to permeate into the interlayer insulating layer 100 during the

6   removal of the double mold 138. As such, permeation of the etchant can be

7   avoided. FIG. 12B is a SEM photograph showing the storage electrode 150 formed

8   according to the preferred embodiment of the present invention. As shown, the

9   defects of the prior fabrication methods are not observed.

10   [0220]   Next, as shown in FIG. 13, a dielectric layer 170 is formed to cover the

11   storage electrode 150, and an upper electrode 180 is formed by a known process to

12   obtain a complete capacitor. The dielectric layer 170 may be an oxynitride (NO)

13   layer, but other materials of sufficiently large dielectric constants (k) may be used as

14   well.

15   [0225]   Referring again to FIGS. 12A, the storage electrode 150 is in contact with

16   the contact plug 115 and has a vase-like cylindrical structure. In particular, the

1 cylindrical wall of the storage electrode is defined by an upper cylindrical wall portion

2 extending between A and B, a lower cylindrical wall portion extending between C

3 and D, and an intermediate cylindrical wall portion extending between B and C.

4 The diameter of the upper cylindrical wall portion and the diameter of the lower

5 cylindrical wall portion increase (taper outwardly) with an increase in a distance from

6 the surface of the bottom wall, and the diameter of the intermediate cylindrical wall

7 portion decreases (tapers inwardly) with an increase in a distance away from the

8 surface of the bottom wall.   According to the preferred embodiment of the present

9 invention, the following relationships are established when configuring the storage

10 electrode 150:

11 $$A \geq C, \quad C > B, \quad \text{and} \quad C > D$$

12 where A is a diameter of the upper cylindrical wall portion at a location farthest from

13 the bottom wall, B is a diameter of the upper cylindrical wall portion at a location

14 nearest to the bottom wall, C is a diameter of the lower cylindrical wall portion at a

15 location farthest from the bottom wall, and D is a diameter of the lower cylindrical

16 wall portion at the bottom wall.

21

1 [0230] The aforementioned dimensional requirements prevent bridging between

2 adjacent storage electrodes and enable in-line monitoring of the critical dimension D

3 of the outer diameter at the bottom of the storage electrode by measuring only the

4 critical dimension A of the outer diameter at the top of the storage electrode during

5 manufacture of the storage electrode.

6 [0235] FIG. 14 illustrates the bridging that can occur if the critical dimension C'

7 of the storage electrode 150 is larger than a critical dimension A'. Further, even if

8 actual bridging does not occur between adjacent storage electrodes, a sufficient

9 processing margin is not ensured unless C' is set to be less than or equal to A'.

10 [0240] The properties of the OCS capacitor according to the present invention

11 and a variety of processing parameters applied in the fabrication of the OCS

12 capacitor were determined through the experimental examples described below. It

13 will be appreciated that the numerical values appearing in the following experimental

14 examples may be varied according to the target height and capacitance of a storage

15 capacitor to be fabricated.

Experimental Example 1

[0245]   The properties of a capacitor fabricated by a conventional method using a single mold were compared with those of a capacitor fabricated by the method according to the present invention using a double mold.

[0250]   Capacitors having 1.6 μm or greater storage electrodes were fabricated using both methods under the same conditions, except that the double mold of the present invention was formed of a 0.5 μm thick BPSG layer as a lower mold and a 1.2 μm thick PE-TEOS layer as an upper mold, whereas the single mold for the conventional method was formed of a single 1.7 μm thick PE-TEOS layer.

[0255]   Referring to FIG. 15, the capacitor fabricated using the single mold showed about 15 twin-bit failures in each cell, which is 3 times more than in the capacitor fabricated using the double mold of the invention, which resulted in about 5 twin-bit failures in each cell.   It is evident that the capacitor fabrication method using a double mold according to the present invention can sharply reduce twin-bit failures in resulting cells.

[0260]   Storage node capacitance Cs was measured for the capacitors fabricated

23

1   by the conventional method and the method according to the present invention.   As

2   shown in FIG. 16, the storage node capacitance Cs for the capacitor fabricated by

3   the method according to the present invention was about 1.5 fF greater for each cell

4   than the storage node capacitance Cs for the capacitor fabricated by the

5   conventional method.   This is because that the storage electrode formed by the

6   method according to the present invention using the double mold has a larger bottom

7   area than that formed by the conventional method using the single mold.

8

9   Experimental Example 2

10   [0265]   The relationship between bit failure and refresh time was investigated for

11   a capacitor having a 1.4 μm high storage electrode fabricated by the conventional

12   method using a single mold and a capacitor having a 1.6 μm high storage electrod

13   fabricated by the method according to the present invention using a double mold.

14   As shown in FIG. 17, the capacitor formed by the method according to the present

15   invention shows an increased refresh time than the capacitor formed by the

16   conventional method at the same single-bit failure levels.   A 4fF-greater

1 capacitance for each cell according to the present invention causes this

2 phenomenon.

3

Experimental Example 3

4

5 [0270]   To screen suitable insulating material layers for the lower mold of the

6 double mold used in the capacitor fabrication method according to the present

7 invention, lower molds were formed of a P-SiH$_4$ layer and a doped BPSG layer,

8 respectively, with an upper mold formed of a PE-TEOS layer.   For storage

9 electrodes formed with the respective double molds, the critical dimension of the

10 outer diameter A at the top of the opening, the critical dimension of the outer

11 diameter C at the second inflection point, and the critical dimension of the outer

12 diameter D at the bottom were measured.   The results are shown in Table 1.

13

14

15

16

Table 1

Material	Critical Dimension "A" of Outer Diameter at the Top (nm)	Critical Dimension "C" of Outer Diameter at Second Inflection Point (nm)	Critical Dimension "D" of Outer Diameter at the Bottom (nm)	Bottom to Top (D : A) Opening Ratio (%)
P-SiH$_4$	215	170	109	51
BPSG	205	192	149	73

[0275]   As shown in Table 1, a doped insulating layer is suitable as the material

layer for the lower mold of the double mold used in the fabrication of a capacitor in

accordance with the present invention.

Experimental Example 4

[0280]   To determine an appropriate concentration of dopants in the lower mold

insulating layer, storage electrodes were fabricated by the method according to the

present invention under the same conditions, but with variations in the

concentrations of dopants, boron, and phosphorous in the BPSG lower mold layer.

Then, the critical dimension of the outer diameter A at the top of the opening, the

critical dimension C of the outer diameter at the second inflection point of the

1   opening, and the critical dimension of the outer diameter D at the bottom of the

2   opening were measured for the respective capacitors.   The results are shown in

3   Table 2.

Table 2

Concentrations of B and P in BPSG layer (% by weight)	Critical Dimension "A" of Outer Diameter at the Top (nm)	Critical Dimension "C" of Outer Diameter at Second Inflection Point (nm)	Critical Dimension "D" of Outer Diameter at the Bottom (nm)	Middle to Top (C : A) Opening Ratio (%)	Bottom to Top (D : A) Opening Ratio (%)
B-2.3/P-2.0	218	206	165	94	76
B-2.51/P-2.45	213	205	171	96	80
B-3.0/P-2.75	200	188	151	94	80
B-3.5/P-3.65	212	216	178	102	82

5

6   [0285]   As shown in Table 1, as the concentrations of B and P in the BPSG layer

7   for the lower mold insulating layer increase, the storage electrodes showed an

8   increase in both the critical dimensions D and C of the outer diameter at the bottom

9   and at the second inflection point due to the increased wet etch rate.   For the

10   storage electrode formed with 3.5% by weight of B and 3.65% by weight of P, the

11   critical dimension C of the outer diameter at the second inflection point was greater

1   than the critical dimension A of the outer diameter at the top, resulting a middle

2   opening ratio of 102%.

3   [0290]   In addition, since the wet etching process functions at the same time as a

4   pre-cleaning process prior to the formation of the storage electrode, the high etch

5   rate of the lower mold insulating layer ensures sufficient pre-cleaning effect.

6   Accordingly, the concentrations of B and P are preferably 2-3% by weight.

7

8   Experimental Example 5

9   [0295]   Experiments were conducted to determine an optimal thickness of the

10   lower mold insulating layer in which the critical dimension of the outer diameter C at

11   the second inflection point can be held no larger than the critical dimension A of the

12   outer diameter at the top of the opening, while maximizing the critical dimension D of

13   the diameter at the bottom of the opening.   In particular, the thickness of a BPSG

14   lower mold layer was varied between 0.3 μm to 0.5 μm, while maintaining a total

15   thickness of the upper and lower mold insulating layers at 1.7 μm.   The resulting

16   storage electrodes were measured for the critical dimension A of the outer diameter

1   at the top of the opening, the critical dimension C of the outer diameter at the second

2   inflection point, and the critical dimension D of the outer diameter at the bottom of

3   the opening.   The results are shown in Table 3.

4

5   Table 3

Thickness of BPSG layer (• m)	Critical Dimension "A" of Outer Diameter at the Top (nm)	Critical Dimension "B" of Outer Diameter at Second Inflection Point (nm)	Critical Dimension "D" of Outer Diameter at the Bottom (nm)	Bottom to Top (D : A) Opening Ratio (%)
0.3	217	164	138	64
0.5	207	198	163	79

6

7   **[0300]**   As shown in Table 3, the bottom opening ratio (D : A) and the critical

8   dimension C of the outer diameter at the second inflection point of the storage

9   electrodes were greater for the BPSG layer having a thickness of 0.3 μm than for the

10   BPSG layer having a thickness of 0.5 μm.

11   **[0305]**   Additional storage electrodes were fabricated using double molds each

12   having a 1.9 μm double mold thickness with different BPSG lower mold layer

1   thickness of 0.5 μm, 0.6 μm, 0.7 μm, and 0.8 μm.   The critical dimension A of the

2   outer diameter at the top of the opening, the critical dimension C of the outer

3.   diameter at the second inflection point, and the critical dimension D of the outer

4   diameter at the bottom of the opening were measured for the respective storage

5   capacitors.   The results are shown in Table 4.

6   Table 4

Thickness of BPSG layer (• m)	Critical Dimension "A" of Outer Diameter at the Top (nm)	Critical Dimension "C" of Outer Diameter at Second Inflection Point (nm)	Critical Dimension "D" of Outer Diameter at the Bottom (nm)	Middle Opening (C : A) Ratio (%)	Bottom Opening (C : A) Ratio (%)
0.5	243	206	183	85	75
0.6	248	216	176	87	71
0.7	235	221	188	94	80
0.8	243	233	186	96	77

7

8   [0310]   As shown in Table 4, even where the thickness of the BPSG layer is

9   increased above 0.5 μm, the bottom opening ratio changes very little, while the

10   critical dimension C of the outer diameter at the second inflection point changes

11   significantly.   Thus, it is evident that once the thickness of the BPSG layer as a

30

1   lower mold reaches a particular level, the critical dimension D of the outer diameter

2   at the bottom of the storage electrode is not substantially affected by increasing the

3   thickness of the BPSG layer.   Therefore, when the lower mold insulating layer is

4   formed of a BPSG layer, the thickness of the BPSG layer is preferably in the range

5   of 0.5-0.6 μm.

6

7   Experimental Example 6

8   [0315]   To determine an optimal anneal temperature to be performed after

9   formation of a BPSG lower mold layer, BPSG layers were formed on respective

10   silicon nitride layers and then annealed at 650°C for 60 min and at 750°C for 10 min,

11   respectively.   Many cracks were observed in the BPSG layer after annealing at

12   750°C, which is greater than the deposition temperature of the silicon nitride layer.

13   Therefore, it is evident that annealing should be performed at a temperature lower

14   than the deposition temperature of silicon nitride layer.

15

Experimental Example 7

[0320]   After annealing a BPSG lower mold insulating layer, an upper mold

insulating layer was formed on the BPSG layer without first cleaning the surface of

the BPSG layer to remove surface defects.   Then, a storage electrode was formed

using a double mold method according to the present invention and then observed

by scanning electron microscopy (SEM).   As a result, as shown in FIGS. 18 and 19,

rings bounding adjacent storage electrodes (so called "wing defects") were observed

at the interface between the upper and lower mold insulating layers of the storage

electrodes.

[0325]   Such wing defects are a cause twin-bit failures and are considered to

result from formation of an amorphous defect layer, which has a high etch rate, on

the BPSG layer as discussed previously.   To remove these defects, the formation of

·a BPSG lower mold insulating layer was followed by removal of a defect layer under

the conditions shown in Table 5.   The process of removing the defect layer was

performed using a sulfuric acid solution.

Table 5

Sample	Suspension Time before Cleaning (hr)	Suspension Time after Cleaning (hr)	Wing Defect
1	18	0	no
2	24	0	no
3	0	8	no
4	0	18	no
5	0	24	no
6	0	48	yes

[0330]   As shown in Table 5, even though the lower mold insulating layer after

annealing is left unprocessed for about 24 hours before cleaning in a sulfuric acid

solution, twin-bit failures can be avoided as in Samples 1 and 2 by the cleaning.

Likewise, as in samples 3, 4 and 5, twin-bit failures can be avoided if the upper mold

layer is formed within 24 hours cleaning in a sulfuric acid solution of the lower mold

layer.

Experimental Example 8

[0335]   Wet etching the upper and lower mold insulating layers was carried out

1 under different conditions, i.e., SC1 for 5 min/HF for 90 sec, SC1 for 7 min/HF for 90

2 sec, and SC1 for 10 min/HF for 90 sec. The lower critical dimension D and the

3 bottom opening ratio (D : A) were measured for the respective storage electrodes.

4 The results are shown in FIG. 20. As shown in FIG. 20, as the wet etching time

5 increases, both the critical dimension D of the outer diameter at the bottom and the

6 bottom opening ratio (D : A) of the storage electrode is increased. Therefore, the

7 critical dimension D of the outer diameter at the bottom of a storage electrode can be

8 appropriately controlled by adjusting the wet etching time.

9

10 [0340] In the method for fabricating a one-cylinder stack (OCS) capacitor using a

11 double mold according to the present invention, the height of the storage electrode

12 can be increased while avoiding twin-bit failures. The OCS capacitor fabrication

13 method also ensures a large critical dimension at the bottom of the storage electrode

14 that is sufficiently large to satisfy capacitance requirements. In addition, no special

15 dielectric material is needed to increase capacitance. It is also possible to in-line

16 monitor a storage electrode being manufactured so that permeation of an etchant

1   into th interlayer insulating lay r and the g neration of d f cts by the etchant

2   permeation can be prevented.   Also, critical dimensions are established ensure a

3   stable support structure and sufficient capacitance.

4   **[0345]**   Although the invention has been described with reference to the preferred

5   embodiments, the preferred embodiments are for descriptive purposes only.   As it

6   will be apparent to one of ordinary skill in the art that modifications of the described

7   embodiments may be made without departing from the spirit and scope of the

8   invention, the scope of the appended claims is not to be interpreted as being

9   restricted to these embodiments.
